

inhomogeneous bar construction

Let  $G$  be a group and  $L$  be an  $A$ -module on which  $G$  acts. Recall that the bar complex consists of

$$C^r(G, L) = \{G\text{-equivariant functions } G^{r+1} \rightarrow L\}.$$

Its typical element is called a cochain.

If you choose a set of representatives for the orbits  $G \backslash G^{r+1}$ , then a cochain is determined by its values on the chosen representatives.

For example,

$$\{1\} \times G^r \hookrightarrow G^{r+1}$$

is such a set of representatives.

Define

$$\bar{C}^r(G, L) = \{\text{all functions } G^r \rightarrow L\}.$$

There is a natural restriction map

$$\begin{aligned} C^r(G, L) &\rightarrow \bar{C}^r(G, L) \\ \phi &\mapsto \bar{\phi} \end{aligned}$$

such that

$$\bar{\phi}(g_1, \dots, g_r) := \phi(1, g_1, \dots, g_r).$$

The map

$$C^r(G, L) \rightarrow \bar{C}^r(G, L)$$

has a inverse; it is given by

$$\bar{C}^r(G, L) \rightarrow C^r(G, L)$$

$$\phi \mapsto \tilde{\phi}$$

where

$$\tilde{\phi}(g_0, \dots, g_r) = g_0 \cdot \phi(g_0^{-1}g_1, \dots, g_0^{-1}g_r).$$

Let us try to transfer the differential on  $C^\bullet(G, L)$  to  $\bar{C}^\bullet(G, L)$ . An obvious attempt is

$$d\phi := \overline{(d\tilde{\phi})}.$$

That is to say, if  $\phi \in \bar{C}^r(G, L)$ , then

$$\begin{aligned} & d\phi(g_1, \dots, g_{r+1}) \\ &= \overline{(d\tilde{\phi})}(g_1, \dots, g_{r+1}) \\ &= (d\tilde{\phi})(1, g_1, \dots, g_{r+1}) \\ &= \tilde{\phi}(g_1, \dots, g_{r+1}) - \tilde{\phi}(1, g_2, \dots, g_{r+1}) + \dots + (-1)^{r+2} \tilde{\phi}(1, g_1, \dots, g_r) \\ &= g_1 \cdot \phi(g_1^{-1} g_2, \dots, g_1^{-1} g_{r+1}) \\ &\quad - \phi(g_2, \dots, g_{r+1}) + \dots + (-1)^{r+2} \phi(g_1, \dots, g_r). \end{aligned}$$

Clearly,  $d^2 = 0$  on  $\bar{C}^\bullet(G, L)$ . The pair

$$(\bar{C}^\bullet(G, L), d)$$

is called the (inhomogeneous) bar complex.

## $H^0$ by inhomogeneous bar complex

An element

$$\phi \in \bar{C}^0(G, L)$$

is a function  $\phi: G^0 \rightarrow L$ . Let  $G^0 = \{*\}$ . The condition  $d\phi = 0$  is equivalent to

$$(d\phi)(g) = g \cdot \phi(*) - \phi(*) = 0$$

for all  $g \in G$ . Thus, we recover

$$H^0(G, L) = L^G.$$

## $H^1$ by inhomogeneous bar complex

Take  $\phi \in \bar{C}^1(G, L)$ . It is a function  $\phi: G \rightarrow L$ . The condition  $d\phi = 0$  is equivalent to

$$d\phi(g_1, g_2) = g_1 \cdot \phi(g_1^{-1}g_2) - \phi(g_2) + \phi(g_1) = 0$$

for all  $g_1, g_2 \in G$ . It is equivalent to

$$\phi(g_1g_2) = g_1 \cdot \phi(g_1) + \phi(g_2)$$

for all  $g_1, g_2 \in G$ .

## $H^1$ by inhomogeneous bar complex, continued

Let us describe

$$d: \bar{C}^0(G, L) \rightarrow \bar{C}^1(G, L).$$

Recall that a 0-cochain  $\eta \in \bar{C}^0(G, L)$  is determined by its unique value, say  $x \in L$ . Then,

$$(d\eta)(g) = g \cdot x - x.$$
